Web Scraping

Hey, web scraping!

You may want to...

- download all videos from a website;
- download all news articles from a media platform;
- download all academic papers from a journal;
- download all tweets/weibo of a specific person.

You may need to spend days and nights downloading these data manually, and you can easily make a lot of mistakes.

Hey, web scraping!

In today's class, we are going to learn about webscraping. In Chinese, it is called 网络爬虫.

What is webscraping?

Using tools to gather data you can see on a webpage. Almost anything you see on a website can be scraped.

It can be done with python, R,... We are doing it on R.

https://www.youtube.com/embed/Ct8Gxo8StBU?enablejsapi=1

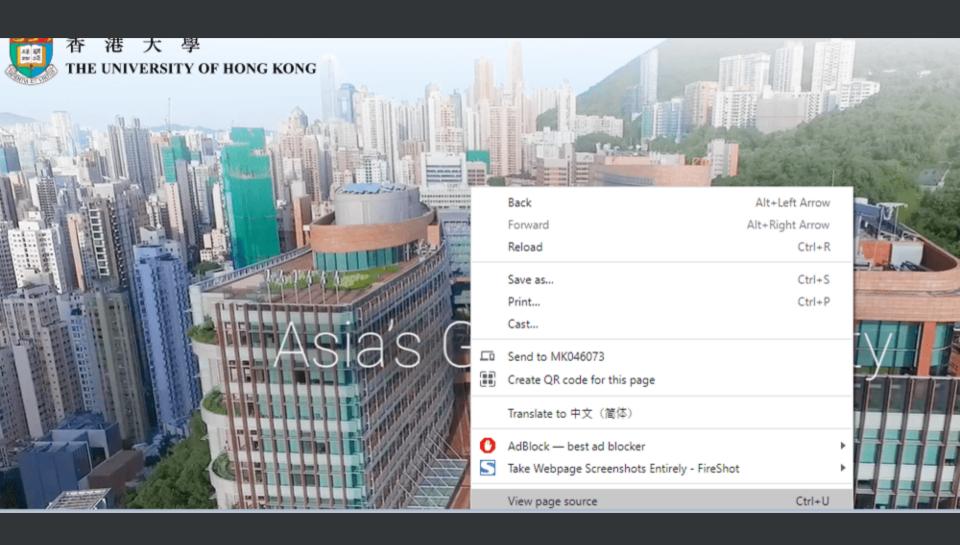

HTML stands for "HyperText Markup Language."

Websites are written on the HTML language, and web scraping is based on reading and interpreting the HTML of a webpage.

But how to find the HTML of a webpage?

Please use Google Chrome as your browser.

If you are not a current user of Google Chrome, download and install one on your laptop. Google Chrome is particularly helpful for analyzing webpages for scraping.

```
2 <!DOCTYPE html>
3 <!--[if lt IE 9]><html class="no-js lte-ie9 lt-ie9lang-en" lang="en"><![endif]-->
4 <!--[if IE 9]><html class="no-js lte-ie9 ie9lang-en" lang="en"><![endif]-->
5 <!--[if gt IE 9]><!-->
6 <html class="no-js" xmlns="http://www.w3.org/1999/xhtml"
    xml:lang="en" lang="en">
  <head>
     <meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
10
     <meta http-equiv="X-UA-Compatible" content="IE=edge" />
11
    <meta name="viewport" content="width=device-width, initial-scale=1, shrink-to-fit=no"</pre>
12
    <meta http-equiv="Content-Style-Type" content="text/css" />
13
    <meta http-equiv="Content-Script-Type" content="text/javascript" />
14
    <link rel="apple-touch-icon" sizes="180x180" href="/assets/img/apple-touch-icon.png">
15
    <link rel="icon" type="image/png" href="/assets/img/favicon-32x32.png" sizes="32x32">
16
    <link rel="icon" type="image/png" href="/assets/img/favicon-16x16.png" sizes="16x16">
17
     <link rel="manifest" href="/assets/img/manifest.json">
18
    <link rel="shortcut icon" href="/assets/img/favicon.ico">
19
    <meta name="msapplication-config" content="/assets/img/browserconfig.xml">
20
    <meta name="theme-color" content="#ffffff">
21
    <noscript><style>
22
```

The data you want to scrape appears in certain place of the HTML. For example, suppose that you want to scrape data from the HKU marketing faculty webpage:

You can find the name and images of the professors from the HTML file:

```
▼ <div class="people-card fadeInUp animated" data-animate="fadeInUp"> flex
   ▼<a href="https://www.hkubs.hku.hk/people/jinzhao-du/" class="el-processed">
     ▶ <noscript> --- </noscript>
       <img decoding="async" width="800" height="800" src=</pre>
       "https://www.hkubs.hku.hk/wp-content/uploads/fly-images/8059/Dr Du Jinzhou 2019-scaled-800x800-ct.jpg
       " data-src="https://www.hkubs.hku.hk/wp-content/uploads/flv-images/8059/Dr Du Jinzhou 2019-scaled-800
       x800-ct.jpg" class="attachment-people-thumbnail ls-is-cached lazyloaded" alt="Prof. Jinzhao DU's por
       tfolio">
     ▼ <div class="people-info">
        <div class="h5">Prof. Jinzhao DU</div> == $0
       </div>
     </a>
   </div>
 </div>
▶ <div class="wgl col-3 people-item">....</div>
▶ <div class="wgl col-3 people-item"> ... </div>
```

And even the link to their photos (see this link for example).

```
▼ <div class="people-card fadeInUp animated" data-animate="fadeInUp"> flex
   ▼<a href="https://www.hkubs.hku.hk/people/jinzhao-du/" class="el-processed">
     ▶ <noscript> --- </noscript>
       <img decoding="async" width="800" height="800" src=</pre>
       "https://www.hkubs.hku.hk/wp-content/uploads/fly-images/8059/Dr_Du_Jinzhou_2019-scaled-800x800-ct.jpg"
       " data-src="https://www.hkubs.hku.hk/wp-content/uploads/fly-images/8059/Dr Du Jinzhou 2019-scaled-800
       x800-ct.jpg" class="attachment-people-thumbnail ls-is-cached lazyloaded" alt="Prof. Jinzhao DU's por
       tfolio">
     ▼ <div class="people-info">
        <div class="h5">Prof. Jinzhao DU</div> == $0
       </div>
     </a>
   </div>
 </div>
▶ <div class="wgl col-3 people-item"> ··· </div>
▶ <div class="wgl col-3 people-item"> ... </div>
```

Secret: Changing the webpage

Suppose that you want to download the names of each individual marketing faculty, what should you do?

First, you need to get the HTML for the webpage.

Second, you need to analyze the HTML to get the desired information --- this is much more difficult.

```
install.packages("rvest")
library(rvest)
url = "https://www.hkubs.hku.hk/people/faculty?
pg=1&staff_type=faculty&subject_area=marketing&track=all"
webpage = read_html(url, encoding = "UTF-8")
print(webpage)
```

Now, you get the HTML source file here. The next thing you need to do it to understand the HTML file, which is very challenging.

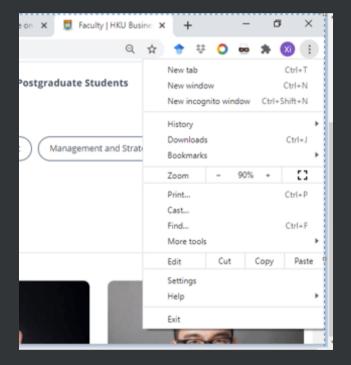

```
> print(webpage)
{html_document}
<html dir="ltr" lang="en-US" prefix="og: https://ogp.me/ns#">
[1] <head>\n<meta http-equiv="Content-Type" content="text/html; charset=UTF-8">\n<meta name="viewp ...
[2] <body class="page-template page-template-people-listing page-template-people-listing-php page ...</pre>
```

To better understand the HTML code, you are strongly recommended to use Chrome as your browser.

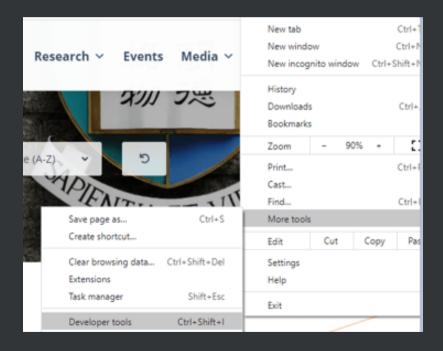

Chrome allows you to check the HTML code in a much more convenient matter.

Open the webpage in your Chrome browser.

Click the upper right Chome setting button of your browser and you will be directed here.

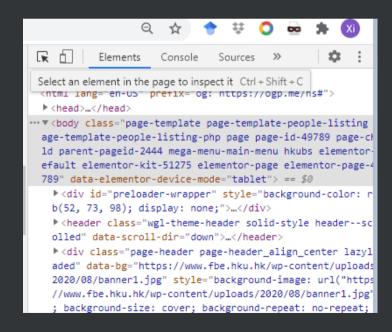

Choose "More tools"...
Choose "Developer tools"...

Click the button and you will get to "select an element in the page to inspect it".

Alternatively, use "Ctrl + Shift + C."

If needed, also click the button to switch between desktop and mobile version.

Take Prof. Du's information as an example. You can see his name appears here in the HTML code. But what does this mean?

```
▼ <div class="listing">
 ▼ <div class="row"> flex
   ▶ <div class="wgl col-3 people-item"> ... </div>
   ▶ <div class="wgl col-3 people-item"> ··· </div>
   ▶ <div class="wgl col-3 people-item"> ··· </div>
   ▶ <div class="wgl col-3 people-item"> .... </div>
   ▶ <div class="wgl col-3 people-item"> ··· </div>
   ▼ <div class="wgl col-3 people-item">
     ▼ <div class="people-card fadeInUp animated" data-animate="fadeInUp"> flex
       <a href="https://www.hkubs.hku.hk/people/jinzhao-du/" class="el-processed">
         ▶ <noscript> • </noscript>
          <img decoding="async" width="800" height="800" src=</pre>
          "https://www.hkubs.hku.hk/wp-content/uploads/flv-images/8059/Dr Du Jinzhou 2019-scaled-800x800-ct.jpg"
          data-src="https://www.hkubs.hku.hk/wp-content/uploads/flv-images/8059/Dr Du Jinzhou 2019-scaled-800x800-c
          t.jpg" class="attachment-people-thumbnail lazyloaded" alt="Prof. Jinzhao DU's portfolio">
         ▼ <div class="people-info">
            <div class="h5">Prof. Jinzhao DU</div> == $0
          </div>
        </a>
       </div>
     </div>
   ▶ <div class="wgl col-3 people-item"> ... </div>
```

https://www.yhutube.kom/e.phadbu@GaZfIfBRI?enablejsapi=1 ed/u0OeZfIfBRI?enablejsapi=1

Here, the name information is within a "div" node.

And this node belongs to a "div" node.

This "div" node further belongs to another "a" node.

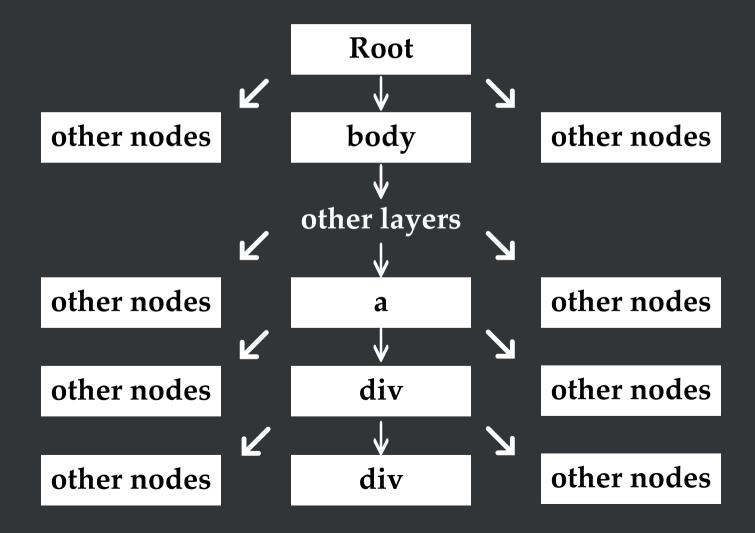

And so on....

We call this is "path": ...div/div/div/a/div/div

You can see that we have various types of nodes, including "div", "a", and "img". You may wonder, "what do these types mean?"

Here, these types are called "tag". For example, an "img" tag is used to mark up an image in the HTML language.

For detailed information, check here.

This is something like your home address:

We have something like...

Country/Province/City/District/Street/Building/Floor/R oom

The path helps us locate nodes and find the content of the nodes.

However, unlike your home address, here each node does not have its name.

For example, we know it is a "div" node (not an "a" node) but there may be multiple "div" nodes.

My building is in a street (not an avenue or road) but there may be multiple streets here.

Let's get all "div" nodes. This can be done by running this:

```
1 nodes <- html_nodes(webpage,xpath = '//div')</pre>
```

You can see that in total we have 262 "div" nodes.

```
print(length(nodes))
```

We want to make the path more accurate to pin down to the "div" nodes that we are interested in. That is, we want to remove other unrelated "div" nodes.

We can do this by putting more restrictions on the path.

https://www.youtube.com/embed/vNOyRZIkC7o?enablejsapi=1

Consider the following code:

```
1 nodes <- html_nodes(webpage,xpath = '//div/div')
2 print(length(nodes))</pre>
```

Here we restrict the parent of the "div" node must also be a "div" node. Now, we have 208 nodes --- still too many.

Consider the following code:

```
1 nodes <- html_nodes(webpage,xpath = '//div[@class="people-info"]/div')
2 print(length(nodes))</pre>
```

Here we restrict the parent of the "div" node must also be a "div" node. Moreover, the its parent node must have a class attribute will is called "people-info."

Now, we only have 16 div nodes selected. These are actually all HKU marketing faculties. Let us print their names:

```
1 nodes <- html_nodes(webpage,xpath = '//div[@class="people-info"]/div')
2 for (node in nodes)
3  print(html_text(node))</pre>
```

You can also use other refinement to select the nodes that you are looking for. For example, the following codes work as well:

```
1 nodes <- html_nodes(webpage,xpath = '//div[@class="h5"]')
2 for (node in nodes)
3  print(html_text(node))</pre>
```

The complete code is here.

```
library(rvest)
url = "https://www.hkubs.hku.hk/people/faculty?
pg=1&staff_type=faculty&subject_area=marketing&track=all"
webpage = read_html(url, encoding = "UTF-8")
nodes <- html_nodes(webpage,xpath = '//div[@class="h5"]')
for (node in nodes)
print(html_text(node))</pre>
```

Exercise

Great! You know have a sense of how to scrape data from the web. It is very preliminary, and you will need a lot more exercises. Let us try the following exercise.

HKU makes press announcements on its official news webpage: https://hku.hk/press/all/

	< 2024
JAN	FEB MAR APR MAY JUN JUL AUG SEP OCT NOV DEC
20 Apr 2024	> HKU's innovative research novelties win 42 awards at the 49th Press Release International Exhibition of Inventions of Geneva
19 Apr 2024	 HKUMed achieves global breakthrough in personalised stem cell treatment for immunodeficiency patients, urges awareness and advocacy
19 Apr 2024	Initial phase of HKU's Tourist Flow Management Scheme begins on Press Release1 May
18 Apr 2024	Mapping Plant Functional Diversity from Space: HKU Ecologists Press Release Revolutionise Ecosystem Monitoring with Novel Field-Satellite Integration

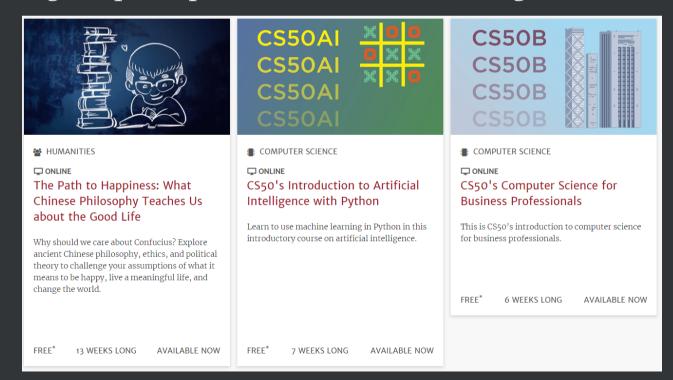

Try to download the titles of these press articles!

URL: https://hku.hk/press/all/

First, let us scrape the titles. We must understand the corresponding HTML code to scrape the data.

```
1 library(rvest)
2 url = "https://hku.hk/press/all/"
3 webpage = read_html(url, encoding = "UTF-8")
4 nodes <- html_nodes(webpage,xpath = '//div[@class="press-item"]/span/a')
5 for (node in nodes)
6 print(html_text(node))</pre>
```

Now, let us visit the Harvard School of Professional Learning: https://pll.harvard.edu/trending

In this exercise, we attempt to scrape the course titles, e.g., "CS50's Introduction to Artificial Intelligence with Python"

Try this exercise yourself!

First, we identify the root of each individual course. We need to inspect the HTML code first.

```
1 library(rvest)
2 url = "https://pll.harvard.edu/trending"
3 webpage = read_html(url, encoding = "UTF-8")
4 nodes <- html_nodes(webpage,xpath = '//h3/a')
5 for (node in nodes)
6 print(html_text(node))</pre>
```

Previously, we have discussed how to scrape text information from a website using a web scraper.

Now, let us consider scraping images from the web.

Let us go back to the HKU marketing faculty webpage:

You can find a link to each photo (in "src" or "data-src" attribute):

Once you get the link, you will have access to the photo.

An example of link: https://www.hkubs.hku.hk/wp-content/uploads/fly-images/11554/FBE_0712_web-scaled-800x800-ct.jpg

So, our first step to get the link information.

```
1 url = "https://www.fbe.hku.hk/people/faculty?
  pg=1&staff_type=faculty&subject_area=marketing&track=all"
2 webpage = read_html(url, encoding = "UTF-8")
3 image_nodes <- html_nodes(webpage,xpath =
   '//div/a/img[@width="800"]')
4 print(length(image_nodes))</pre>
```

But that's not enough. We not only want to get the nodes, but also need the link to each of the nodes. The link appears in the "src" or "data-src" attribute.

But that's not enough. We not only want to get the nodes, but also need the link to each of the nodes. The link appears in the "src" or "data-src" attribute.

```
image_nodes <- html_nodes(webpage,xpath = '//div/a/img[@width="800"]')
for (image in image_nodes)
{
    photourl <- html_attr(image, "data-src")
    print(photourl)
}</pre>
```

```
for (image in image_nodes)

for (image in image_nodes)

photourl <- html_attr(image, "data-src")

print(photourl)

download.file(photourl,

paste0(toString(number),'_HKU_Photo.jpg'), mode = 'wb')

number = number + 1

}</pre>
```

The compete code is here.

```
1 url = "https://www.fbe.hku.hk/people/faculty?
   pg=1&staff type=faculty&subject area=marketing&track=all"
 2 webpage = read html(url, encoding = "UTF-8")
   image nodes <- html nodes(webpage,xpath = '//div/a/img[@width="800"]')</pre>
 4 \text{ number} = 1
   for (image in image nodes)
 5
     photourl <- html attr(image, "data-src")</pre>
     print(photourl)
     download.file(photourl,
 9
10
                    paste0(toString(number),' HKU Photo.jpg'), mode = 'wb')
     number = number + 1
11
12 }
```

Static vs. Dynamic Websites

https://www.youtube.com/embed/hlg6q6OFoxQ?enablejsapi=1

Dynamic Websites

What we learned in today's class works well for static websites. But it does not work equally well on dynamic websites. If you want to scrape data from a dynamic website, you may need to use some more advanced tools.

Dynamic Websites

If you want to scrape data from a dynamic website, there is a tool called "selenium". We also have a packaged called "RSelenium" in R.

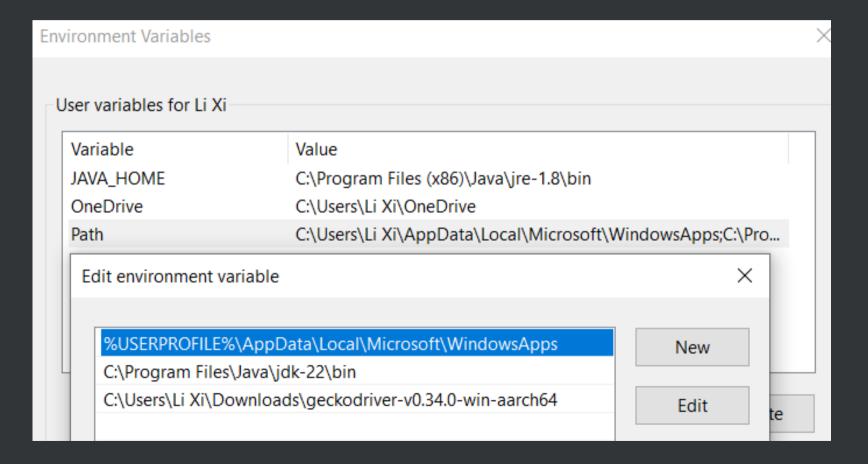

The selenium tool allows your scraper to visit a webpage like a human-being. That is, if you write a scraper with selenium, your scraper will also be able to scroll down your pages, click buttons, enter your password, etc.

Dynamic Websites (Optional)

To scrape from a dynamic website, you need to:

- Install package "RSelenium"
- Install Firefox browser
- Download and install Java JDK and add its path to your system environment variable "PATH"
- Download and unzip Firefox Driver and add its path to your system environment variable "PATH"

Dynamic Websites (Optional)

Demonstration (Optional)

1 library(RSelenium) 2 driver <- rsDriver(browser="firefox", port=4990L, verbose=F, chromever = NULL) 3 remote driver <- driver[["client"]]</pre> 4 remote driver\$open() 5 remote driver\$navigate("https://ximarketing.github.io") 6 element <- remote driver\$findElement(using = "xpath", value = '//a[contains(text(), "Teaching")]') 7 element\$clickElement() 8 Sys.sleep(5) 9 element <- remote driver\$findElement(using = "xpath", value = '//a[contains(text(), "Algorithms")]') 10 element\$clickElement() 11 Sys.sleep(5) 12 element <- remote driver\$findElement(using = "xpath", value = '//input') element\$sendKeysToElement(list("2425")) Sys.sleep(5) 14 15 element <- remote driver\$findElement(using = "xpath", value = '//button') 16 element\$clickElement() 17 Sys.sleep(5) 18 remote driver\$close()

Thank you! Enjoy scraping!
